

Last time: QR iteration

QR iteration is the standard solver in solving eig. val. problems for dense matrix

Today: Other eigenvalue solvers and SVD solvers

---

Previously: Householder transform  $\leftarrow$  zeroes out several coordinates using reflection

New: Givens transform  $\leftarrow$  zeroes out a single coordinates using rotation

$$G := \begin{bmatrix} c & s \\ -s & c \end{bmatrix} \in \mathbb{R}^{2 \times 2}$$

rotate counterclockwise by  $\theta$

$$\text{choose } c, s \text{ we can have } G^T v = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

In  $\mathbb{R}^n$ , define a Givens matrix

$$G(i, j, \theta) := \begin{bmatrix} 1 & \dots & 0 & \dots & 0 & \dots & 0 \\ \vdots & & \vdots & & \vdots & & \vdots \\ 0 & \dots & c & \dots & s & \dots & 0 \\ \vdots & & \vdots & & \vdots & & \vdots \\ 0 & \dots & -s & \dots & c & \dots & 0 \\ \vdots & & \vdots & & \vdots & & \vdots \\ 0 & \dots & 0 & \dots & 0 & \dots & 1 \end{bmatrix} \begin{matrix} i^{\text{th}} \text{ row} \\ j^{\text{th}} \text{ row} \end{matrix}$$

$$c := \frac{x_i}{\sqrt{|x_i|^2 + |x_j|^2}}, \quad s := \frac{-x_j}{\sqrt{|x_i|^2 + |x_j|^2}}$$

$$G^T(i, j, \theta) \begin{bmatrix} x_1 \\ \vdots \\ x_i \\ \vdots \\ x_j \\ \vdots \\ x_n \end{bmatrix} = \begin{bmatrix} x_1 \\ \vdots \\ x'_i \\ \vdots \\ 0 \\ \vdots \\ x_n \end{bmatrix} \quad (x'_i = \sqrt{x_i^2 + x_j^2})$$

Complex case:  $G := \begin{bmatrix} c & e^{i\phi}s \\ -e^{-i\phi}s & c \end{bmatrix} \in \mathbb{C}^{2 \times 2}$

choose  $c, s, \phi \in \mathbb{R}$  such that

$$G^T \begin{bmatrix} u \\ v \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}, \quad \begin{aligned} r^2 &= |u|^2 + |v|^2 \\ r &\in \mathbb{R} \end{aligned}$$

Note:  $G^T$  is equivalent to the Householder from  $\begin{bmatrix} u \\ v \end{bmatrix}$  to  $\begin{bmatrix} r \\ 0 \end{bmatrix}$ .

and define Givens matrix similarly

$$G^T(i, j, \theta, \phi) \begin{bmatrix} v_1 \\ \vdots \\ v_i \\ \vdots \\ v_j \\ \vdots \\ v_n \end{bmatrix} = \begin{bmatrix} v_1 \\ \vdots \\ v'_i \\ \vdots \\ 0 \\ \vdots \\ v_n \end{bmatrix} \quad (v'_i = \sqrt{|v_i|^2 + |v_j|^2})$$

### • Jacobi method

Let  $A \in \mathbb{C}^{n \times n}$  be Hermitian

Goal: Perform similarity transform to make  $A$  diagonal

Idea: Let the sum of off-diagonal entries be

$$N(A) = \sum_{i \neq j} |a_{ij}|^2$$

Want to find  $J \in \mathbb{C}^{n \times n}$  such that

$$B = G^{-1}AG \text{ and } N(B) < N(A)$$

Choose  $G$  be Givens matrix

Analysis: Let  $G = G(s, t, \theta, \phi)$

$$N(B) = \sum_{i \neq j} |b_{ij}|^2$$

$$= \|B\|_F^2 - \sum_{i=1}^n |b_{ii}|^2$$

$$\downarrow = \|A\|_F^2 - \sum_{\substack{i=1 \\ i \neq s, t}}^n |a_{ii}|^2 - |b_{ss}|^2 - |b_{tt}|^2$$

when  $G$  is unitary

$$\|G^T A G\|_F = \|A\|_F$$

$$a_{ii} = b_{ii} \quad \forall i \neq s, t$$

Givens preserved the norm

$$\begin{aligned}
 &= N(A) + |a_{ss}|^2 + |a_{tt}|^2 - |b_{ss}|^2 - |b_{tt}|^2 \\
 &= N(A) + \underbrace{2|b_{st}|^2 - 2|a_{st}|^2}_{\text{choose } \theta, \phi \text{ to zero out } b_{st}}
 \end{aligned}$$

$|b_{tt}|^2 + |b_{st}|^2 = |a_{tt}|^2 + |a_{st}|^2$   
 $|b_{ss}|^2 + |b_{ts}|^2 = |a_{ss}|^2 + |a_{ts}|^2$

Implementation: (Classical Jacobi)

Let  $A_1 = A$ . Given a tolerance  $\epsilon > 0$

For  $k = 1, 2, 3, \dots$

Find  $|a_{st}^{(k)}| = \max_{i \neq j} |a_{ij}^{(k)}|$  ( $A_k = (a_{ij}^{(k)})_{n \times n}$ )

If  $|a_{st}^{(k)}| < \epsilon$ , return  $A_k$

otherwise compute  $G_k^T = G^T(s, t, \theta, \phi)$  to zero out  $a_{st}^{(k)}$

compute  $A_{k+1} = G_k^T A_k G_k$

Convergence: At each step

$$N(A_k) \leq (n^2 - n) \max_{i \neq j} |a_{ij}^{(k)}|^2 = n(n-1) |a_{st}^{(k)}|^2$$

$$N(A_{k+1}) = N(A_k) - 2|a_{st}^{(k)}|^2$$

$$\begin{aligned}
 &\leq N(A_k) \left[ \underbrace{1 - \frac{2}{n(n-1)}}_{=: q_n \in [0, 1]} \right] \\
 &\leq \dots \leq N(A_1) q_n^k \rightarrow 0 \text{ as } k \rightarrow +\infty
 \end{aligned}$$

The convergence is locally quadratic.

Cost Let  $N(A_k) \sim O(\epsilon_{\text{mach}})$

$$\Rightarrow k \sim \log(\epsilon_{\text{mach}}) / \log q_n \sim n^2 \log(\epsilon_{\text{mach}})$$

Each step requires  $O(n)$  flops.

$$\text{Total cost} \approx O(n^3 \log(\epsilon_{\text{mach}}))$$

- Remark: 1) Searching for the largest off-diagonal entry is expansive. Can improve by a lot of different trick.  
e.g. eliminate all off diagonal entries one-by-one,  
or, set a threshold such that as long as we scan through an entry whose magnitude is larger than the threshold, elimination is implemented.
- 2) Jacobi method is easily parallelizable with each thread eliminating different row / column
- 3) Sparsity is not preserved in Jacobi method
- 4) Not used in practice, slower than standard QR in many cases
- 

Other methods:

- Bisection method / Sturm sequence methods:
    - compute a specific <sup>(small)</sup> subset of eig. values. e.g.  $p^{\text{th}}$  eig. val.
    - much faster  <sup>$O(n)$  cost</sup> to find a small subset of eig. val. of  $A$
  - Divide-and-Conquer
    - Tear the tridiagonal Schur form in half, compute each in parallel, and then combine them together
    - Fast in practice
-

- Computing the SVD

Goal:  $A \in \mathbb{C}^{m \times n}$

Find unitary  $U \in \mathbb{C}^{m \times m}$ ,  $V \in \mathbb{C}^{n \times n}$ .

$$\Sigma = \text{diag}(\sigma_1, \dots, \sigma_{\min\{m, n\}}) \in \mathbb{R}^{m \times n}$$

such that  $A = U \Sigma V^*$

### Naïve algorithm

Step 1: Compute  $C = A^*A$

Step 2: Apply QR iteration to  $C$

Bad idea because: 1) Forming  $A^*A$  is costly

2) Information is lost in  $A^*A$

ex.  $A = \begin{bmatrix} 1 & 1 \\ \sqrt{\epsilon_{\text{mach}}} & 0 \\ 0 & \sqrt{\epsilon_{\text{mach}}} \end{bmatrix} \quad \left( \kappa_2(A) = \sqrt{\frac{\epsilon_{\text{mach}} + 2}{\epsilon_{\text{mach}}}} \rightarrow 1 \right)$

compute on floating point system  $\rightarrow f(A^*A) = fl \left( \begin{bmatrix} 1 & \sqrt{\epsilon_{\text{mach}}} & 0 \\ 1 & 0 & \sqrt{\epsilon_{\text{mach}}} \end{bmatrix} \begin{bmatrix} 1 & 1 \\ \sqrt{\epsilon_{\text{mach}}} & 0 \\ 0 & \sqrt{\epsilon_{\text{mach}}} \end{bmatrix} \right)$

$$= \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \leftarrow \text{singular!}$$

Mimicking the two-phase method of QR iteration,

the standard SVD solver for dense  $A$  is the following

### Golub-Kahan Method

Idea: Implicitly apply QR iteration to  $A^*A$

## Step 1 Reduce $A$ to upper bidiagonal form

Goal: Apply different unitary matrix on left and right of  $A$

$$A = \begin{bmatrix} x & x & x & x \\ x & x & x & x \\ x & x & x & x \\ x & x & x & x \\ x & x & x & x \\ x & x & x & x \end{bmatrix} \xrightarrow[\substack{U_1^* \\ F_1}]{U_1^* \cdot} \begin{bmatrix} x & x & x & x \\ 0 & x & x & x \\ 0 & x & x & x \\ 0 & x & x & x \\ 0 & x & x & x \\ 0 & x & x & x \end{bmatrix} \xrightarrow[\substack{\cdot V_1 \\ [F_2]}]{[I_1]} \begin{bmatrix} x & x & 0 & 0 \\ 0 & x & x & x \\ 0 & x & x & x \\ 0 & x & x & x \\ 0 & x & x & x \\ 0 & x & x & x \end{bmatrix}$$

$U_1^* A$   $U_1^* A V_1$

$$\xrightarrow[\substack{U_2^* \\ [I_2 \\ F_3]}]{U_2^* \cdot} \begin{bmatrix} x & x & 0 & 0 \\ 0 & x & x & x \\ 0 & 0 & x & x \\ 0 & 0 & x & x \\ 0 & 0 & x & x \\ 0 & 0 & x & x \end{bmatrix} \xrightarrow[\substack{\cdot V_2 \\ [I_3 \\ F_4]}]{U_2^* \cdot} \begin{bmatrix} x & x & 0 & 0 \\ 0 & x & x & 0 \\ 0 & 0 & x & x \\ 0 & 0 & x & x \\ 0 & 0 & x & x \\ 0 & 0 & x & x \end{bmatrix} \Rightarrow \dots \Rightarrow \begin{bmatrix} x & x & 0 & 0 \\ 0 & x & x & 0 \\ 0 & 0 & x & x \\ 0 & 0 & 0 & x \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

$U_2^* U_1^* A V_1$   $U_2^* U_1^* A V_1 V_2$   $U_4^* U_3^* U_2^* U_1^* A V_1 V_2 =: B$

Work for Golub-Kahan bidiagonalization

$\approx$  twice of QR fact.

$\approx 2(2mn^2 - \frac{2}{3}n^3)$  complex flops

Remark: Cost can be reduced by first computing

(R-SVD)

(Lawson-

Hanson-

chan

Bidiagonalization)

QR fact. of  $A = QR$ . then perform bidiagonalization to  $R$ . This is saving when  $m \gg n$ .

Step 2: Apply QR iter. to  $B^T B$   $\nwarrow$  bidiagonal form

Again, forming  $B^T B$  is not a wise choice from numerical standpoint.

Need to apply QR and RQ step implicitly.

Details are omitted (Implicit Q theorem... ..)

Remark: Jacobi method can be extended similarly.

---

Mature algorithms can be found in LAPACK
